ULTRASOUND IMAGING

**Ever wondered what your muscles look like?
Take a peek beneath the skin with ultrasound imaging.**

Ultrasound imaging uses a handheld device called a transducer to send sound waves into the body and detect echoes returning from tissues. Different tissues reflect sound differently, allowing muscles, tendons, fat, and bone to be distinguished in the image.

Ultrasound is widely used in sports science, biomechanics, and rehabilitation. It can be used to study muscle architecture and tendon behaviour or to assess injuries and monitor recovery.

How does this demo work?

An ultrasound transducer is placed on the skin over a muscle. It captures live images of the tissues beneath the skin. You can watch your own muscles change shape as you move, flex, and relax.
